DOM and **Events**

Building Modern Web Applications - VSP2019

Karthik Pattabiraman Kumseok Jung

Recap from Lecture 1

- 1. Recap from Lecture 1
- 2. DOM APIs
- 3. DOM Traversal
- 4. DOM Manipulation
- 5. DOM Events

Recap from Lecture 1: DOM

 Hierarchical representation of the contents of a web page – initialized with static HTML

- Can be manipulated from within the JavaScript code (both reading and writing)
- Allows information sharing among multiple components of web application

DOM: an evolving entity

DOM is highly dynamic!

Why study DOM interactions?

 Needed for JS code to have any effect on webpage (without reloading the page)

UBC

- Uniform API/interface to access DOM from JS
- Does not depend on specific browser platform

NOTE

- We'll be using the native DOM APIs for many of the tasks in this lecture
- Though many of these can be simplified using frameworks such as jQuery,
 it is important to know what's "under the hood"
- We assume a standards compliant browser!

DOM APIS

- 1. Recap from Lecture 1
- 2. DOM APIs
- 3. DOM Traversal
- 4. DOM Manipulation
- 5. DOM Events

Selecting HTML Elements

 You can access the DOM from the object window.document and traverse it to any node

UBC

- However, this is slow often you only need to manipulate specific nodes in the DOM
- Further, navigating to nodes this way can be error prone and fragile
 - Will no longer work if DOM structure changes
 - DOM structure changes from one browser to another

Selecting HTML Elements

- With a specified id
- With a specified tag name
- With a specified class
- With generalized CSS selector

Method 1: getElementById

- Used to retrieve a single element from DOM
 - IDs are unique in the DOM (or at least must be)
 - Returns null if no such element is found

```
var id = document.getElementById("Section1");
if (id === null) throw new Error("No element found");
```

Method 2: getElementsByTagName

 Retrieves multiple elements matching a given tag name ('type') in the DOM

 Returns a read-only array-like object (empty if no such elements exist in the document)

```
var images = document.getElementsByTagName("img");
for (var i = 0; i < images.length; i++){
   images[i].style.display = "none";
}</pre>
```

Method 3: getElementsByClassName

- Can also retrieve elements that belong to a specific CSS class
 - More than one element can belong to a CSS class

```
var warnings = document.getElementsByClassName("warning");
if (warnings.length > 0){
   console.log("Found " + warnings.length + " elements");
}
```

Important point: Live Lists

Both getElementsByClassName and getElementsByTagName return
 live lists

- List can change after it is returned by the function if new elements are added to the document
- List cannot be changed by JavaScript code adding to it or removing from it directly though
- Make a copy if you're iterating through the lists

Selecting Elements by CSS selector

 Can also select elements using generalized CSS selectors using querySelectorAll() method

UBC

- Specify a selector query as argument
- Query results are not "live" (unlike earlier)
- Can subsume all the other methods
- querySelector() returns the first element matching the CSS query string, null otherwise

CSS selector examples

```
"#nav" // Any element with id="nav"
   "div" // Any <div> element
   ".warning" // Any element with "warning" class
6
   "#log span" // Any <span> descendant of id="log"
   "#log > span" // Any <span> child element of id="log"
10
   "body > h1:first-child" // first <h1> child of <body>
12
   "div, #log" // All <div> elements and element with id="log"
14
```

Invocation on DOM subtrees

 All of the above methods can also be invoked on DOM elements not just the document

- Search is confined to subtree rooted at element
- Example: Assume element with id="log" exists

```
var log = document.getElementById("log");
var error = log.getElementsByClassName("error");
if (error.length === 0){ ... }
```

Class Activity

Assume the page contains a <div> element with ID id, which contains a series of images (nodes)

Write a function that takes two arguments, id and interval. At each interval, the images must be "rotated", i.e., image0 will become image1, image1 will become image2, etc.

```
function changeImages(id, interval){
}
```

To repeat the execution of a given function f at a specific interval
 (e.g. 1000 ms): setInterval(1000, f);

DOM Traversal

- 1. Recap from Lecture 1
- 2. DOM APIs
- 3. DOM Traversal
- 4. DOM Manipulation
- 5. DOM Events

Traversing the DOM

 Since the DOM is just a tree, you can walk it the way you'd do with any other tree

UBC

- Typically using recursion
- Every browser has minor variations in implementing the DOM, so should not be sensitive to such changes
 - Traversing DOM this way can be fragile

Before accessing or manipulating the DOM...

Problem

- When your JS code executes, the page might not have finished loading
 - The DOM tree might not be fully instantiated / might change!

window.onload

- Event that gets fired when the DOM is fully loaded (we'll get back to events later...)
- You can give a callback function to execute upon proper loading of the DOM.
- Your DOM manipulation code should go inside that function

```
1 // Using DOM Level 1 API -- not recommended
2 window.onload = function(){ /* Access the DOM here */ }
```

Properties for DOM Traversal

- parentNode: Parent node of this one, or null
- childNodes: A read only array-like object containing all the (live)
 child nodes of this one

 nextSibling, previousSibling: The next and previous siblings of a node (in the order in which they appear in the document)

Other node properties

- nodeType: 'kind of node'
 - Element node: 1
 - o Text node: 3
 - Comment node: 8
 - Document node: 9
- nodeValue: Textual content of Text of comment node
- nodeName: Tag name of a node, converted to upper-case

Class Activity: Find a Text Node

 We want to find the DOM node that has a certain piece of text, say "text"

- Return true if text is found, false otherwise
- We need to recursively walk the DOM looking for the text in all text nodes

```
function search(node, text){
    /* ... */
};
var result = search(window.document, "Hello world!");
```

Class Activity: Find a Text Node

Solution:

```
function search(node, text){
       if (node.nodeType === 3 && node.nodeValue === text){
          return true;
      else if (node.childNodes){
          for (var i = 0; i < node.childNodes.length; i++){</pre>
             var found = search(node.childNodes[i], text);
             if (found) return found;
10
11
       return false;
12
  | };
   var result = search(window.document, "Hello world!");
```

Class Activity

 Write a function that will traverse the DOM tree rooted at a node with a specific id, and checks if any of its sibling nodes and itself in the document is a text node, and if so, concatenates their text content and returns it.

 Can you generalize it so that it works for the entire subtree rooted at the sibling nodes?

DOM Manipulation

- 1. Recap from Lecture 1
- 2. DOM APIs
- 3. DOM Traversal
- 4. DOM Manipulation
- 5. DOM Events

Adding and removing nodes

 DOM elements are also JavaScript Objects (in most browsers) and consequently can have their properties read and written to

- Can extend DOM elements by modifying their prototype objects
- Can add fields to the elements for keeping track of state (e.g., visited node during traversals)
- Can modify HTML attributes of the node such as width etc. changes reflected in browser display

Creating New and Copying Existing DOM Nodes

- Creating New DOM Nodes
 - Using either document.createElement("element") OR
 document.createTextNode("text content")

```
var newNode = document.createTextNode("hello");
var elNode = document.createElement("h1");
```

- Copying Existing DOM Nodes: use cloneNode
 - Single argument can be true or false
 - True: deep copy (recursively copy all descendants)
 - new node can be inserted into a different document

```
var existingNode = document.getElementById("my");
var newNode = existingNode.cloneNode(true);
```

Inserting Nodes

 appendChild: Adds a new node as a child of the node it is invoked on. node becomes lastChild

• insertBefore: Similar, except that it inserts the node before the one that is specified as the second argument (lastChild if it's null)

```
var s = document.getElementById("my");
s.appendChild(newNode);
s.insertBefore(newNode, s.firstChild);
```

Removing and replacing nodes

Removing a node n: removeChild

```
1 n.parentNode.removeChild(n);
```

Replacing a node n with a new node: replaceChild

```
var edit = document.createTextNode("[redacted]");
n.parentNode.replaceChild(edit, n);
```

Class Activity

 Write a function newdiv that takes two parameters: a node n and a string id. The function should replace node n by making it a child of a new <div> element with id = id.

Class Activity

 Write a function newdiv that takes two parameters: a node n and a string id. The function should replace node n by making it a child of a new <div> element with id = id.

DOM Events

- 1. Recap from Lecture 1
- 2. DOM APIs
- 3. DOM Traversal
- 4. DOM Manipulation
- 5. DOM Events

Registering Event Handlers: DOM 1.0

- Use on{event} as the handler for {event}
 - No caps anywhere. e.g., onload, onmousemove

```
var elem = document.getElementById("mybutton");
element.onclick = function(event){
   this.style.backgroundColor = "#fff";
   return true;
};
```

- this is bound to the DOM element on which the onclick handler is defined – can access its properties through this[prop]
- 2. return value of false tells browser not to perform the default value associated with the property (true otherwise)

Registering Event Handlers: DOM 2.0

 The DOM 1.0 method is clunky and can be buggy. Also, difficult to remove event handlers

- DOM 2.0 event handlers
 - addEventListener for adding a event handler
 - removeEventListener for removing event handlers
 - stopPropagation and stopImmediatePropagation for stopping the propagation of an event

DOM 2.0: addEventListener

 Used to add an Event handler to an element. Does NOT overwrite previous handlers

UBC

- Arg1: Event type for which the handler is active
- Arg2: Function to be invoked when event occurs
- Arg3: Whether to invoke in the 'capture' phase of event propagation (more later) false by default

```
var elem = document.getElementById("mybutton");
elem.addEventListener("click", function(event){
   this.style.backgroundColor = "#fff";
   return true;
});
```

DOM 2.0: addEventListener

 Does not overwrite previous handlers, even those set using onclick, onmouseover etc.

 Can be used to register multiple event handlers – invoked in order of registration (handlers set through DOM 1.0 model have precedence)

```
var elem = document.getElementById("mybutton");
elem.addEventListener("click", function(event){
    alert("Hello");
});
elem.addEventListener("click", function(event){
    alert("World");
});
```

DOM 2.0: removeEventListener

- Used to remove the event handler set by addEventListener functions, with the same arguments
 - No error even if the function was not set as event handler

```
var clickHandler = function(event){
   alert("Clicked");
};
var elem = document.getElementById("mybutton");
elem.addEventListener("click", clickHandler);
elem.removeEventListener("click", clickHandler);
```

Event Handler Context

 Invoked in the context of the element in which it is set (this is bound to the target)

- Single argument that takes the event object as a parameter –
 different events have different properties, with info about the event
 itself
- Return value is discarded not important
- Can access variables in the scope in which it is defined, as any other
 JS function
 - Can support closures within Event Handlers

Class Activity

- Consider an HTML containing 3 buttons with ids reset, increment, and done
- Write a single handler function (i.e., popup) for the click event of each of the 3 buttons to display a message (str1 + str2) using the alert function
 - str1 is determined at runtime when setting the event handler for the button b,
 and should not be stored in the global context
 - str2 is determined based on the event target at the time of its invocation e.g.,
 event.target

```
window.onload = function(){
  var setupBtn = document.getElementById("reset");
  var runBtn = document.getElementById("increment");
  var doneBtn = document.getElementById("done");
  setupBtn.addEventListener("click", /* ??? */);
  runBtn.addEventListener("click", /* ??? */);
  doneBtn.addEventListener("click", /* ??? */);
};
```

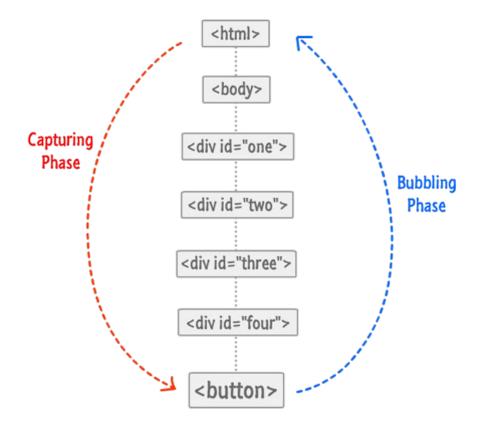

Event Propagation

- Events triggered on an element propagate through the DOM tree in 2 consecutive phases
- UBC

- Capture phase: Event is triggered on the topmost element of the DOM and propagates down to the event target element
- Bubble phase: Event starts from the event target element and 'bubbles up' the
 DOM tree to the top
- Exception: for the target element itself
 - For the target element itself, the W3C standards considers a target phase
 - All handlers registered for the target element are always registered for the target phase – the bubble/capture phase argument is ignored when registering handlers (see later)
 - Events may therefore trigger handlers on elements different from their targets

Capture and Bubble Phases

Event Propagation Setup

 To associate an event handler with the capture phase of event propagation, set the third parameter of addEventListener to true

```
var div1 = document.getElementById("one");
div1.addEventListener("click", handler, true);
```

 The default way of triggering event handlers is during the bubble phase (3rd argument is false)

Capture and Bubble Phases

```
var div1 = document.getElementById("one");
div1.addEventListener("click", handler1, true);
var div2 = document.getElementById("two");
div2.addEventListener("click", handler2, true);
```

Capture Phase

- Assume that the <div> element 'two' is clicked.
- handler1 is invoked before handler2 as both are registered during the capture phase.

Bubble Phase

- Assume that the <div> element 'two' is clicked.
- handler2 is invoked before handler1 as they are both registered during the bubble phase.

Stopping Event Propagation

 In the prior example, suppose handler1 and handler2 are registered in the capture phase

```
var handler = function( clickEvent ){
  clickEvent.stopPropagation();
};
```

 Then handler2 will never be invoked as the event will not be sent to div2 in the capture phase

stopPropagation, preventDefault, stopImmediatePropagation

 An event handler can stop the propagation of an event through the capture/bubble phase using the event.stopPropagation function

UBC

- Other handlers registered on the element are still invoked however
- To prevent other handlers on the element from being invoked and its propagation, use event.stopImmediatePropagation
- To prevent the browser's default action, call the method event.preventDefault

Class Activity

 Consider the JS sample code in prop.js. In what order are the messages in the event handler functions displayed?

UBC

 If you wanted to stop the event propagation in the bubble phase beyond div3, how will you do it?
